

MACHINE LEARNING

In Q1 to Q11, only one option is correct, choose the correct option:

1. Which of the following methods do we use to find the best fit line for data in Linear Regression?
- A) Least Square Error B) Maximum Likelihood
- C) Logarithmic Loss D) Both A and B

Ans: (a)

2. Which of the following statement is true about outliers in linear regression?
- A) Linear regression is sensitive to outliers B) linear regression is not sensitive to outliers
- C) Can't say D) none of these

Ans:(a)

3. A line falls from left to right if a slope is _____?
- A) Positive
B) Negative
C) Zero
D) Undefined

Ans: (b)

4. Which of the following will have symmetric relation between dependent variable and independent variable?

- A) Regression
B) Correlation
C) Both of them
D) None of these

Ans: (b)

5. Which of the following is the reason for over fitting condition?
- A) High bias and high variance B) Low bias and low variance
- C) Low bias and high variance D) none of these

Ans: (c)

6. If output involves label then that model is called as:
- A) Descriptive model B) Predictive modal
- C) Reinforcement learning D) All of the above

Ans: (b)

7. Lasso and Ridge regression techniques belong to _____?
- A) Cross validation B) Removing outliers
- C) SMOTE D) Regularization

Ans: (d)

8. To overcome with imbalance dataset which technique can be used?
- A) Cross validation B) Regularization
C) Kernel D) SMOTE

Ans:(a)

9. The AUC Receiver Operator Characteristic (AUCROC) curve is an evaluation metric for binary classification problems. It uses _____ to make graph?

- A) TPR and FPR
B) Sensitivity and precision
C) Sensitivity and Specificity
D) Recall and precision

Ans: (a)

10. In AUC Receiver Operator Characteristic (AUCROC) curve for the better model area under the curve should be less.

- A) True B) False

Ans: (b)

11. Pick the feature extraction from below:
- A) Construction bag of words from a email
 - B) Apply PCA to project high dimensional data
 - C) Removing stop words
 - D) Forward selection

Ans: (b)

In Q12, more than one options are correct, choose all the correct options:

12. Which of the following is true about Normal Equation used to compute the coefficient of the Linear Regression?

- A) We don't have to choose the learning rate.
- B) It becomes slow when number of features is very large.
- C) We need to iterate.
- D) It does not make use of dependent variable.

Ans (b),(c),(d)

Q13 and Q15 are subjective answer type questions, Answer them briefly.

13. Explain the term regularization?

14. Which particular algorithms are used for regularization?

15. Explain the term error present in linear regression equation?

Answers 13: Regularization is one of the most important concepts of machine learning. It is a technique to prevent the model from overfitting by adding extra information to it. Sometimes the machine learning model performs well with the training data but does not perform well with the test data. It means the model is not able to predict the output when deals with unseen data by introducing noise in the output, and hence the model is called overfitted. This problem can be deal with the help of a regularization technique. This technique can be used in such a way that it will allow to maintain all variables or features in the model by reducing the magnitude of the variables. Hence, it maintains accuracy as well as a generalization of the model. It mainly regularizes or reduces the coefficient of features toward zero. In simple words, "In regularization technique, we reduce the magnitude of the features by keeping the same number of features."

Answer 14: There are three main regularization techniques, namely:

- Ridge Regression
- LASSO (Least Absolute Shrinkage and Selection Operator) Regression
- Elastic-Net Regression

Answer 15: In a linear regression model, the normality assumption (i.e., the error term is normally distributed) NOT required for calculating unbiased estimates. In this post, we'll discuss under what situations we would need this normality assumption, why it is reasonable to make such an assumption, and how to check if the errors are normally distributed. The following is what a typical linear regression model would look like in the population.

Linear Regression Model in Population: $Y = BX + E$

- The response variable (Y) can be written as a linear combination of explanatory variables (X)
- B are the unknown population parameters (fixed values) that we would estimate from the sample data.
- E is the error term that represents the difference between the true value (expressed by βX) and the observed response value in the population. We assume that there could be many different response values (Y) for a given value of X in the population. In other words, conditional on X, both Y and ϵ could take different values. Therefore, Both the response variable and the error term are random variables.
